Abstract 6

Millions of children worldwide are "left behind" when their parents migrate away for work.

Parents' labor migration increases household income but decreases parental care, thereby

exerting mixed influences on child development, including educational performance. To

what extent do different arrangements of parental migration affect children's schooling

performance in the short term? Studying the case of China, I obtained a sample of four 11

thousand junior high school students from a nationally representative two-wave panel 12

survey. I differentiated household migration arrangements of any one parent, of mother

only, of father only, and of both parents. I measured children's educational performance by 14

standardized cognitive test score and academic exam grades. For causal inference, I built 15

difference-in-differences models with propensity score matching. Results show that the new 16

left-behind children's performance at school dropped slightly compared to that of 17

non-left-behind peers. Father-only migration is negatively associated with children's 18

cognitive abilities, while mother-only migration is negatively associated with children's 19

academic grades.

Newly Left-Behind Children's Educational Performance Drops Slightly After Parents Migrated

25 Introduction

Millions of children are resided in their home communities but separated from their parents as either one or both parents have migrated for work. These are the so-called "left-behind children" or "stay-behind children." They are common in migrant-sending regions, such as Latin America, Sub-Sahara Africa, East Europe, and large parts of Asia. Researchers estimated that one-sixth of Mexican children (DeWaard et al., 2018), one-fifth of Bulgarian children (Popova, 2018), and one-fourth of Chinese children were living apart from their migrating parents (NBS et al., 2017).

How are stay-behind children faring when parents have migrated? Scholars have obtained mixed results due to the differential effects of parental migration. Consider children's education. According to the review articles by Brauw (2019) and Van Hook and Glick (2020), labor migrants send remittances back, which can fund children's schooling as well as improve their nutritional and living conditions. The inflow of remittances, however, cannot substitute for the loss of parental care. Parental migration decreases the amount and quality of parental guidance, protection, and support. It is uncertain how these two opposing effects together shape children's educational performance, which merits empirical investigation.

A challenge arises when we want to assess the causality between parent's migration and children's educational achievement. Experiments can unveil causal relations, but it is unfeasible and unethical to design an experiment that randomly assigns parents to migrate without their children. Alternatively, we can infer causality from a quasi-experimental design – that is, when the cause is on par with random assignment to participants in the analysis, conditional on identification assumptions (Cunningham, 2021).

In this thesis, my research question is: To what extent do parental migration affect

- the educational performance of left-behind children in the short term? I chose China as the
- 50 case and analyzed data from a two-wave panel survey. The nationally representative
- $_{51}$ sample includes children in both urban and rural areas. I developed a
- 52 difference-in-differences model for causal inference and applied propensity score matching
- 53 for robustness check. The outcome was measured with children's cognitive test score and
- academic exam scores. I demonstrate that parental migration reduces the educational
- performance of children staying behind, but only to a small extent.

Literature Review

7 Theoretical Framework

56

81

Between parental migration and children's education, the mechanisms trace to two
theoretical frameworks. One is the resource generation model. It holds that parental
migration brings forth greater resources in the form of economic capital. Economic capital
is, in Bourdieu's words, "immediately and directly convertible into money and may be
institutionalized in the form of property rights" (2002, p. 16). Economic capital is
transferable to human capital, which is the stock of "skills, talents, health, and expertise"
in people that enhance their productivity (Botev et al., 2019; Goldin, 2016). D. Yang
(2008) noted that in the Philippes, a sharp depreciation of peso increased the amount of
remittances from migrant laborers working abroad. This subsequently boosted children's
school enrollment and educational expenditure. In China, Chang et al. (2019) interviewed
migrant workers and their family members. Oftentimes, they found that labor migration
presented the only way to sustain their children's education and livelihood.

The other theoretical model is the family disruption model. Children flourish under parental nurturing care. This term refers to the "stable environments that promote health and adequate nutrition, protect from threats, and provide opportunities for learning and responsive, emotionally supportive and developmentally enriching relationships" (Black et al., 2021, p. 1). Parental migration decreases nurturing care, thereby hindering children's developmental outcomes. The loss of nurturing care slows children's accumulation of human capital. Hong talked to a group of left-behind children at a rural school (Hong & Fuller, 2019). These students expressed the utter sense of loneliness "with no advocate, no support and with no one looking out for them" (p. 13). Many of them felt indifferent to school grades, and some even longed to ditch school to pursue a free, independent life (p. 14).

Researchers obtained mixed results regarding how parental migration affects

children's education. Botezat and Pfeiffer (2020) studied the case of Romania and found a positive effect of parents' migration on academic grades of adolescents aged eleven to fifteen. L. Wang et al. (2019) collected data from junior high school students in central China and found no effect of parental on left-behind children's achievement in mathematical test. Studying four Chinese provinces, Brauw and Giles (2017) showed that as ample migration opportunities appeared in villages, enrollment to senior high school decreased. Nguyen (2016) demonstrated that parental migration was associated with lower cognitive capabilities among Indian and Vietnamese children aged five to eight. The inconsistency can result from factors such as the left-behind children's age and gender, the migrant parent's original domicile and eventual destination, and the arrangement of which parent migrate for how long.

Parental migration immediately disrupts family structure, which in turn lowers academic performance of children. It takes longer time for parental migration to generate resources that improve children's educational attainment. I propose the first hypothesis:

 H_1 In the short term, parental migration negatively affect the cognitive development and academic performance of children left-behind.

Researchers have studied whether the impact differ between mother absence and 98 father absence in the context of labor migration. Y. Xu et al. (2019) adopted a gg fixed-effects propensity score weighting model on cross-sectional data collected from 100 seventh and ninth graders in rural areas across China. They found that the absence of 101 father only or both parents had "little or no association with negative outcomes" on children's academic and cognitive performances. Only-mother absence, however, showed a 103 "strong association with negative outcomes" (p. 1646). Chen et al. (2019) conducted 104 structural equation modeling on the cross-sectional data collected from fourth to seventh 105 graders in the countryside of one province. They found that mother migration was 106 "negatively associated with children's social competence and academic performance," while 107

father migration had no direct effects on the two outcomes (pp. 860-861).

In China, the social norms designate men as breadwinners and women as caregivers.

Studies noted that in some Asian and Latin American societies, children are more likely to
accept fathers' migration than mothers' (Murphy, 2022). Left-behind children may even
resent their migrant mothers, viewing them as transgressing on the expected care-giving
roles. I propose the second hypothesis:

 H_2 In the short term, mother migration negatively affect the cognitive development and academic performance of children left-behind, while father migration does not show a effect.

17 China's Context

Three features make China a suitable case for studying left-behind children. The 118 first feature is the huge scale of internal labor migration. According to the National Bureau 119 of Statistics, the year 2021 recorded 292.5 million in-country migrant workers (NBS, 2022). 120 They form the backbone of essential industries, such as retail, delivery, transportation, and 121 manufacturing. The number of left-behind Chinese children reached 68.7 million in 2015 122 (NBS et al., 2017). The second feature is the neoliberal welfare regime. Neoliberalism 123 extends the logic of the market to most spheres of human life. Driven by the neoliberal 124 doctrine, the government shifts its responsibilities of social services and welfare to 125 individuals and communities. Since China initiated pro-market reforms in the 1980s, the 126 state has reduced its welfare provisions and passed them to individuals and families 127 (Duckett, 2020). The third is the authoritarian control against citizens. According to Gu 128 (2021) and Zhang (2018), the hukou (household registration) system controls people's 129 mobility by binding a household's public welfare access with its place of registry. One can 130 move out of town freely but cannot change hukou freely. For rural household members 131 moving to the city, it takes months – if not years – to apply for a new hukou. Before 132 receiving urban hukou, they only enjoy limited access to public service in the host city, 133

including public education for children. Migrant laborers had organized strikes and protests, only to meet with police crackdown (Chan & Selden, 2017). Facing financial and policy constraints, many migrant laborers have to leave children in their hometowns (Gu, 2021; Zhang, 2018).

The existing research about China's left-behind children has three major 138 shortcomings. The first is that most literature focuses on children left behind in rural areas 139 while neglecting the urban counterparts. The National Bureau of Statistics stated that the 140 number of urban left-behind children had been growing and expected that the trend would 141 continue (NBS et al., 2017). My sample includes urban left-behind children as well. The 142 second shortcoming lies in sampling and research design. Some studies suffer from a 143 limited sample size of less than one thousand participants or a limited geographic coverage 144 of one to a few towns (Jin et al., 2020; Y. Liu et al., 2021; Shu, 2021; F. Yang et al., 2022). 145 Others only estimate correlation using cross-sectional data (Akezhuoli et al., 2022; Jin et 146 al., 2020). These studies could have applied causal inference techniques like fixed effect, 147 matching, or inverse probability of treatment weighting. Others s The third shortcoming 148 lies in the measurement of outcome. Chang et al. (2019) and L. Wang et al. (2019) 149 measured students' educational performance with the test score of only one academic 150 subject, namely mathematics. To tackle these limitations, I adopted a nationally 151 representative two-wave panel dataset. I included the test results of multiple subjects to 152 measure comprehensive academic achievement. 153

154 Methods

155 Sampling

I obtained the data from the China Education Panel Survey (CEPS) (NSRC, n.d.). 156 It is a nationally representative, school-based survey featuring junior high school students. 157 The survey administrator is the National Survey Research Center at Renmin University of 158 China. The survey team adopted multi-stage stratified probability proportional to size 159 sampling and administered a paper-and-pencil questionnaire to each participant. The 160 baseline survey took place in the 2013-2014 academic year with a sample size of about twenty thousand students in the seventh and ninth grades. These students were nested in 162 438 classrooms of 112 schools in 28 urban districts or rural counties. The follow-up survey 163 in the 2014-2015 academic year lost track of the ninth grade cohort and only surveyed 9449 of the seventh grade cohort. I further restricted the sample to students staying with both 165 parents at the original domicile at the baseline survey. To deal with missing values, I 166 adopted list-wise deletion for dependent, independent, and control variables. The final 167 sample size amounted to 4088. 168

169 Measurement

I explored two categories of educational performance: cognitive and academic abilities. One key dependent variable, the student's cognitive skill, was measured by a fifteen-minute standardized test. The test covered three types of reasoning: verbal, visuospatial, and numerical. The CEPS research team calculated the raw score based on the Item Response Theory and then standardized the score with a mean of zero and standard deviation of one.

Another dependent variable concerned students' academic performance. This was
measured by the total scores of mid-term exams in Chinese, mathematics, and English as
provided by each school. Throughout junior high school, students study these subjects,
which are included in the entrance exam to senior high school. Within each cohort in one

particular school, teachers adopt the same syllabus and administer the same exams during 180 a given assessment period. Therefore, test scores for core subjects are reliable indicators of 181 learning performance in the same school and cohort. I aligned different grading scales (full 182 mark of 100, 120, and 150 for one subject) to the hundred-point scale. After the 183 conversion, I checked for abnormal values outside the 0-100 range. 31 observations were 184 outliers, accounting for less than one percent of the sample. I trimed the values of subject 185 exam score with minimum of zero and maximum of one hundred. In this way, I can limit 186 the impact of outliers while retaining these observations in the sample. After trimming, I 187 aggregated the subject exam scores to obtain a total score of a 300-point scale. 188

The key independent variable, the parental migration status, was identified by two 189 items in the parent survey. In both the baseline and the follow-up surveys, parents specified 190 the family members living in the same household at the time. I constructed four treatment 191 dummy variables measuring migration arrangements: any parents absent, only father 192 absent, only mother absent, and both parents absent. These arrangements are mutually 193 exclusive. The control group consisted of parents staying with their children throughout at 194 both the baseline and the follow-up surveys. I then removed the observations that reported 195 parental divorce or death. These type of parental absence are irrelevant to migration. 196

197 Data analysis

I adopted R for all the analyses, the fixest package for econometric modeling
(Berge et al., 2022), and the modelsummary package for presenting the results
(Arel-Bundock, 2022). I built a two-way fixed effect model in a difference-in-differences
(DID) design, following Bai and colleagues' (2018; 2020) approach. The model served to
analyze the educational outcome of children newly left behind by parents vis-a-vis that of
children staying together with parents. I first specified an unrestricted and unadjusted
model:

$$\Delta score_{i,j,k} = \alpha + \beta \cdot migr_i + \gamma \cdot C_j + \lambda \cdot C_k + \theta \cdot score_{i,j;1} + \varepsilon_{i,j,k}$$

For student i in class j in baseline and class k in endline, $\Delta score_{i,j}$ is the change in test 205 score between baseline and follow-up surveys, $migr_i$ is the treatment dummy variable, C_i 206 and C_k are respectively the classroom fixed-effects at baseline and follow-up, and $score_{i,j,k;1}$ 207 is the test score at baseline. Classroom fixed-effect can account for differences due to 208 time-invariant factors at the classroom level and above, as students nested in the same 200 class are also in the same school and county. About one-sixth of the students were 210 reassigned into new classroom at the end of baseline academic year. This necessitates 211 adding the wave-two classroom fixed-effect. 212

The model is unrestricted because it does not restrict on the coefficient associated with the baseline scores. The model is unadjusted as it does not adjust for additional covariates. Theoretically, it is unnecessary to include covariates that vary over group but remain constant over time; They would cancel out in the two-way fixed effect model (Huntington-Klein, n.d.). The standard errors were clustered at the classroom level.

In addition, I present an unrestricted and adjusted DID model:

$$\Delta score_{i,j,k} = \alpha + \beta \cdot migr_i + \gamma \cdot C_j + \lambda \cdot C_k + \theta \cdot score_{i,j,k;1} + \zeta \cdot X_i + \varepsilon_{i,j,k}$$

where X_i is the vector of covariates capturing the characteristics of children, their parents, and their households. The control variables were measured in the baseline survey. This version of model lifts the restriction that covariates from the baseline survey would be associated with a coefficient that equals one. 223 Results

224 Descriptive Statistics

The table below summarizes the changes in migration status in the sample. All 4088 children were living together with parents in one household in baseline, but about fifteen percent saw at least one parent migrated during the two waves of survey. In these new migrant households, only-mother migration and only-father migration each accounted for two out of five cases. The remaining one-fifth was both-parents migration.

Table 1

Parental migration status at follow-up survey.

		N	%
Parental Migration	No	3452	84.4

233 Regression Analysis

The unrestricted DID models support my hypothesis one – newly left-behind adolescents are more likely to perform worse in cognitive and academic abilities than their non left-behind counterparts. If a household sees any parent migrated, the child's cognitive test score and total exam grade would decrease relative to that of children whose parents stay with them, holding everything else constant. Parental migration is linked to is -0.09 SD in cognitive test score and -0.09 points in academic exam grades. Both relationships are slight in strength.

The results only partially support the hypothesis two – mother migration has a
more negative effect than father migration. This holds true for academic abilities. Children
from only mother migrate households are associated with -0.04 points relative to that of
children whose parents stay along. The performances of children with both parents
migrated or only father migrated do not show statistically significant difference from the
non left-behind children. Regarding cognitive abilities, the reverse is true. Children with
only mother migrated do not show statistically significant difference from the non

left-behind children. Children with only father absent are associated with (-0.14 SD), and both parents absent (-0.10 SD) compared to the non left-behind children.

The adjusted DID models produce similar results compared to the unadjusted models, with only one exception. That is, for the cognitive skills, the both-parent-absent coefficient saw a change of statistical significance level from five percent level to ten percent level.

Some predictors are strong in both models of cognitive and academic abilities.

These are children's age and educational aspiration as well as parents' expectation on

children. In terms of age, the older students' scores drop relatively more than younger

students'. One year older in age is associated with -0.07 SD for standardized cognitive test

and -1.23 points for academic exams. Parent's expectation for children completing

university and children's own aspiration for finishing university are associated with higher

scores. The effect sizes are 0.01 SD and 0.07 SD for standardized cognitive test,

respectively; and 0.29 points and 1.82 points for academic exams, respectively.

Several predictors are strong in the model of academic grades but not in that of cognitive scores. These are children's gender and self-reported health, and the years of

parental education. Girls outperform boys by 4.49 points in academic exams, but do not
show advantage in cognitive test. Students who consider themselves healthier are
associated with higher scores in academic exams. Parents with more education are
associated with their children's higher scores in academic exams. If the years of parental
education of the best-educated among the two increase by one, it would be linked to a 0.88
points increase in the child's academic exam grade. These three predictors are not
significant for cognitive outcomes.

Preschool attendance is associated with higher cognitive outcomes 0.07 SD, but its effect for academic outcomes is not significant.

Matching

276

Parental migration is not a randomly assigned treatment. One technique to tackle 278 this selection bias is matching. This method works by pairing a unit in the treatment group 279 with one or several units in the control group based on observable covariates. Popular 280 choices include coarsened exact matching (CEM) (Waldman, 2022) and nearest-neighbor 281 propensity score matching (PSM) (H. Xu & Xie, 2015). As Greifer (2022) introduced, 282 CEM is superior in achieving balance as it optimizes the entire joint distribution of 283 covariates. The downside is that it leaves many units without an exact match and discards 284 these unmatched units. The nearest-neighbor matching examines all the treated units and 285 selects the closest control unit to be paired. The eligibility as the "closest" can be determined with the differences in propensity score. Propensity score denotes the 287 probability of receiving treatment based on the specified covariates. Nearest-neighbor PSM does not try to optimize any condition; each pairing ignores how other pairing will or have 289 occurred (Greifer, 2022). King and Nielsen (2019) argued against this matching method as 290 it risks more "imbalance, model dependence, and bias" for highly balanced data.

Using the MatchIt package (Ho et al., 2022), I performed matching with all the covariates of the adjusted DID model. I first attempted CEM, but it left most units unmatched and resulted in a tiny sample. I then made do with the PSM. I combined exact matching (based on the student's county of residence) and nearest neighbor PSM (based on the other covariates) following the configuration of Bai et al. (2018). Exact matching based on county of residence preserves the original geographic distribution. The propensity score was estimated using a logistic regression of the treatment on the covariates. The matching ratio was set at one treatment unit with up to three control units. The matching produced absolute standardized mean differences below 0.1 for all but a few covariates, suggesting an improved overall balance.

Alike are the results from DID models with matching (DIDM) and those without. In the models of cognitive abilities, I obtained negative, statistically significant coefficients on the treatment variables in the any parent migrated household and only father migrated households. In the models of academic abilities, the treatment variables' coefficients are negative and statistically significant for the any parent migrated households and only mother migrated households. The significance level of any parent migration drops to ten percent. In all models, the magnitudes of the statistically significant coefficients are similar. I present the unadjusted DIDM models below and the adjusted DIDM models in the appendix.

342

Discussion

This thesis proposed a model to assess causality between parents' migration and 318 their stay-behind children's educational performance in the short run. I built econometric 319 models in the difference-in-differences design to analyze data from the 2013-2014 and 320 2014-2015 rounds of China Education Panel Survey. Results suggest that parental 321 migration is, in the short run, negatively associated with children's educational 322 performance as measured by academic exams and standardized cognitive tests. I further 323 examined whether the effect varies across different arrangements of parental migration. 324 Results indicate that father-only migration is negatively associated with children's 325 cognitive abilities, while mother-only migration is negatively associated with children's academic abilities. In all scenarios, the educational performance of newly left-behind children only decreased slightly compared to that of non-left-behind peers.

My research has limitations in sampling due to data constraint. Regarding sample 329 size, the treatment group for the both-parents migration is small, lowering the statistical 330 power. Regarding identification, I could only identify parental migration through such a 331 condition: parental absence from a household without parental divorce or death. This is 332 because the CEPS questionnaire asked if parents were living in the household, but did not 333 ask why parents were absent. It is possible that some parents were jailed or hospitalized. 334 These types of absence would be wrongly attributed to migration. Besides, I could not 335 control for the migration history of parents, which are not included in the CEPS data. 336 Possibly, some parents out-migrated at an earlier date, returned before the baseline survey, 337 and migrated away again during the survey period. Their children might better cope with 338 parental absence during the survey period, yet they would be mistaken as the newly 339 left-behind. These limitations may bias the estimation.

Limitations also arise from unaccounted endogeneity and exogeneity. As Chen et al. (2009) stated in their research on left-behind children, endogenous factors may create

selection bias. When migration opportunities arise, some parents may believe that leaving children behind would hamper children's education, thereby giving up the opportunity. 344 Some other parents may believe that their children's schooling would not suffer from 345 parental absence, thereby embarking on migration. Parental beliefs of this sort are 346 unavailable in CEPS data. Exogenous factors may create omitted variable bias. Suppose 347 that a natural hazard hit many counties of a province in the sample. This shock can 348 simultaneously increase parents' out-migration and reduce stay-behind students' grades 340 (Chen et al., 2009). I could not account for such shocks as CEPS data does not include 350 detailed geographic information. 351

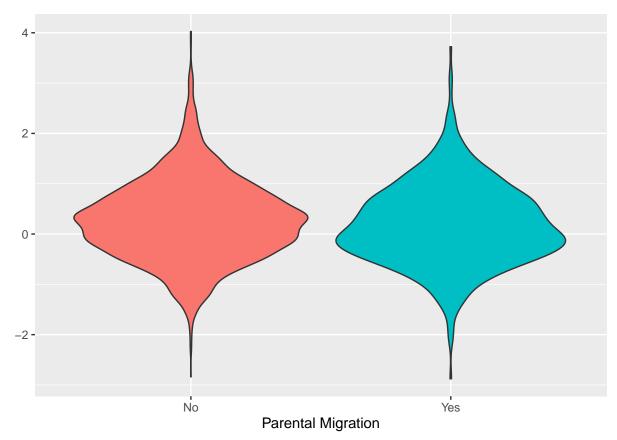

From my research, we can find new directions for scholarly inquiry. First, when the 352 CEPS team releases the next round of data, researchers can capitalize a the three-wave 353 panel dataset to build multi-period DID models. This would facilitate examination of the 354 parallel trend assumption. Second, researchers can try novel methods. Machine learning, 355 for example, can estimate the heterogeneous effects across subgroups (R. Liu, 2021). 356 Synthetic control can evaluate the aggregate outcome of "large-scale but infrequent 357 interventions" at municipal or provincial levels (Abadie, 2021), such as the policy 358 experimentations that liberalize the hukou system in certain cities (X. Wang, 2020). Third, researchers can go beyond outbound migration to study return migration of parents (Liang & Li, 2021). Only a few publications, such as that of Z. Liu et al. (2018), have explored return migrants and their stay-behind children in the Chinese context. 362

Let us consider the policy implications for China. The small reduction of newly left
behind children's schooling performance by no means suggest that policies can remain as
they are. The slight reduction is only the short-term consequence. Longer duration of
parental migration may hamper educational performance to a greater extent. Besides,
educational performance is only part of human development outcomes (Antia et al., 2020).
Other outcomes like mental health and non-cognitive skills are also subjected to parental
absence's influence. Policymakers should reduce institutional barriers at destination cities,

 $_{\rm 370}$ $\,$ opening more doors for parents to migrate together with their children. Meanwhile, schools

371 should dedicate more advisory and counseling support to children who stay behind.
